Hey Claude, could you help me please. I am having issues,

Of course, happy to help. Your message cut off after "I am having issues," so I'm not sure yet which one you're hitting.

From the handoff doc, the last thing on the list was the green-screen problem on your iPad: the buttons and sheets show up, but the pony and ground don't render, and the Revolver dial won't drag. Is that what you're dealing with, or is it something different?

If it's something else, just tell me what you see on the screen and what you were trying to do. Plain words are perfect.

No we are way off on that sheet. Googles servers or something went down because a bunch of Sparks went offline. And Sparks held all of my context on the project. Like gigs. Gigs and gigs. And then when he is tapped I come and use free Claude cause you're still smarter. ^^ but lack all the context cause I'm too poor for both, so. You just rebuilt that, thanks I reeeeeealy appreciate it. I have weird white triangles on my model (I'm just trying to get to the point where I can START modeling) almost almost bugs man, bugs. So the isolated modeler lighting is way too bright, regular game is too dark for modeler, somewhere in middle or I would rather game lighting than that ultra bright. So you just cracked the fucking code and figured out how to smooth everything. And we found old modules you made for pass through and st3d whatever the hell in tools. So we took that tech, made sure it fit the bible and design doc, and now it's good. But the holes and the organs. I need you're beautiful brain please, please please. No one can figure it out, not even you. Check, that the organs are even the same type of model as the pony is that the issue, I can get ANY of you guys to take that Claude pass through tech, and make it the hole system and organ system in the game. I mean expanded of course. But Claude, no one knows what a hole is, that organ bag is FLOATING IN SPACE LIKE A SPOOKY GHOST and the urethra off the back is not connected (may show) but it does not create a hole with the back node to allow me to see into the actual holy motherfuck body. My core and singular assignment basic principle we have to nail before I can get an education and help my life Jesus. I have Google training on pictures of holes right now. Any ideas you see?

Ran 4 commands, read memory

Still reading your file. I found the hole tool and the fused skin, and now I'm checking where the organs sit compared to the body, plus the lighting.

Ran 5 commands, updated memory

Still working: I can't run the 3D view here, but the skin builder is plain math I can test, so I'm checking the white triangles and the hole logic directly.

Ran 9 commands, shared files, updated memory

I found why the holes show nothing and why the organs drift, and I patched both. I can't run the 3D view here, so I haven't seen it on screen. What I did test is the skin-building math on its own, in code, and it behaves as intended. The new [index.html](#) is below.

Why you couldn't see into the body. The skin is one shell, and the body was a solid with no inside. A hole carved into it made a dead-end pocket, so it never opened into a body cavity. That's also why the urethra and gut tube never produced a hole to look into.

The fix: a hollow body.

- The trunk now has a real wall about 7 cm thick and an empty organ bay behind it.
- In my test the outer skin and the inner bay were two separate surfaces without holes. With either hole cut, they joined into one, so the holes now open into the body.
- The inside wall is tinted wet pink.
- The dark lining around a hole used to leak onto the far side of the body, and now it stays at the opening.
- There's a new  **Hollow body** button in the Organs sheet, in case you want solid back.

Why the organs floated. They were drawn for the starting pony and never followed your chest and rear nodes. Walking, ragdoll and your own edits left them behind. Two other bits of code were also fighting over their position, and I removed both.

- The organs now refit to the trunk every frame: position, tilt, roll, length, height and width.
- The anus and urethra tubes attach to their hole nodes, and the throat end follows the jaw.
- The soft green glow inside the pony was stuck at the world origin. It now travels with the organs and switches off when they're hidden.

White triangles. About 90 points on the body had lighting directions pointing backwards, which shows up as white or black specks. I made the skin use its own surface direction at any point where the two disagree. In my test that went from about 13 bad points to zero.

Lighting. Modeler is now close to the game look, with a gentle key light instead of a floodlight. Regular game is a little brighter. It's one block near the top of the file if you want it nudged either way.

Here's what to try on the iPad:

1. Make sure  FUSED is on, then open Organs and use Skin off, or tap the  hole's rim and zoom in.
2. Look into the back hole.
3. Tell me what you see (a screenshot helps).

If something looks off, say whether it's the hole, the organs, or the specks, and in which mode.

Two limits for now. The organs don't yet stretch for a very long neck or a moved head, only the throat end follows. Also, a hole you place somewhere with no cavity behind it, like the head, is still a pocket.

Index

Code·HTML

Adding a ghost-skin toggle and planning easier hole placement.

Seeing your screenshots now. The console shows the skin crashing each time a hole is added, then switching itself off, which brings the specks back. I'm checking that plus the walking and hole controls.

Ran 4 commands, updated memory, shared files

I found what caused the specks coming back and the wall of errors, and fixed it. The pink ball and the camera feel I'm only partly sure about. I haven't seen any of this on your iPad, so this round is still based on your screenshots.

Why the errors and specks returned. Every time a hole was added, the skin kept drawing from the old body for a moment. It crashed on the new hole, over and over. After 60 crashes the game switched the fused skin off for good, and that brought the old broken-looking geometry back. Now the skin rebuilds the moment a hole is added, and a few errors in a row no longer shuts it off.

The white specks on the hooves. The hooves were thinner than the skin grid could draw, so they broke into specks. I gave every part a minimum thickness. The hooves get slightly thicker, which you probably won't notice.

Walking after you let go.

- When you lift your finger she now settles within about 20 cm.
- The follow speed is calmer.
- Finger-steering is switched off while the Hole tool is open, so placing a hole no longer sends her walking or eats your tap.

Holes.

- After you place one, drag your finger over the body and the hole slides along the skin.
- The hole bar has **+** Bigger and **-** Smaller buttons.
- The first choice is now "Plain hole (no tube)". A plain hole has nothing attached and is just an opening into the body.
- The red ring is thinner.
- The "not quite what I pictured" look is still the old design. Tell me what you picture and I'll change it.

Organs and the pink ball. Opening the Organs sheet now makes the skin see-through the first time. There's a  button to switch that on and off. The pink ball is most likely the mare parts seen poking through the opaque skin, but I can't confirm that from the screenshot. With see-through on, please screenshot the mare view again.

Still unfixed. The camera feeling weird, because I can't tell which part you mean. Can you tell me what it does and when, such as "it swings when I drag" or "it won't follow her"?

You assumed wrong and because of that fixed not a thing. Nothing. None of that is done. Those errors came up immediately, I never tried placing a hole. Black and white triangle. More now. Can't access the game with the biiiiiig fucking undismissable error sign. Stop everything and prepare a handoff with our literal every word in chat please.
